## Part 1: Select up to three hardening tools and methods to implement

**1) Baseline configurations - create policy:** A documented set of specifications within a system that is used as a basis for future builds, releases, and updates. Common uses are to restore a system to a previous baseline after a network outage, or unauthorized changes on a baseline.

**2) Multifactor authentication (MFA):** A security measure which requires a user to verify their identity in two or more ways to access a system or network. MFA options include a password, pin number, badge, one-time password (OTP) sent to a cell phone, fingerprint, and more. This can help protect against brute force attacks and similar security events. MFA can be implemented at any time, and is mostly a technique that is set up once then maintained. Additionally, it eliminates the temptation to use shared credentials.

**3) Firewall maintenance:** Firewall maintenance entails checking and updating security configurations regularly to stay ahead of potential threats. This can happen regularly. Firewall rules can be updated in response to an event that allows abnormal network traffic into the network. This measure can be used to protect against various DDoS attacks.

## Part 2: Provide and explain 1-2 recommendations

Baseline configurations enforce consistency, can establish a rule book for reference, and shape or create policy. Within this baseline configuration or policy, a rule must be established that any and all admin credentials, or user credentials, are not kept at default settings and/or used ongoing, as default. Additionally, policy must mandate that no credentials are shared. This can help mitigate future breaches. Baseline configurations can be established once, with bi-annual updates and/or reviews recommended.

MFA and firewall maintenance should be updated regularly. Both aid in revolving hardening and best, safe practices for password management practices. Both reduce the attack surface significantly.
